1. Given a non-empty integer array, find the minimum number of moves required to make all array elements equal, where a move is incrementing a selected element by 1 or decrementing a selected element by 1.

You may assume the array's length is at most 10,000.

Input:

int A[]: the input array.

int N: length of A.

Output:

int minMoves.

Solution. Let us formulate this problem first. Function $F(T)$ to indicate the total movements when the final equal number is T . So we have:

$$F(T) = \sum_{i=1}^N |x_i - T|$$

The problem is to find the minimum of the $F(T)$. This reminds me of one of the most important properties of median: **Median minimizes the sum of Absolute Deviations.** I would like to prove it later. Now if we all agree with the statement, what we should do next is very simple:

Step 1. Find the median M of the array.

Step 2. Calculate $F(M)$.

Step 3. Return $F(M)$ as the final result.

The time complexity of *Step 1* can be $O(n)$ with a divide-and-conquer strategy, which I have mentioned in the *Assignment 2*. The time complexity of *Step 2* is obviously $O(n)$ and *Step 3* is $O(1)$. Therefore, the total time complexity is $O(n)$.

Now, let us prove the above-mentioned statement that Median minimizes the sum of Absolute Deviations.

First of all, I would like to point out some wrong or weak statements. Some say that we must choose the final T from the elements in the array to minimize the $F(T)$, which is definitely wrong for that if the length is even and then we can choose any number between the middle two elements as the final T . Also, some say that choosing average can cause wrong output, then median is the optimal choice. It is just a guess, not a mathematical proof.

Proof 1. Here, I would firstly use derivatives to illustrate why median is optimal choice and provide another proof with basic maths. We all know:

$$\frac{d|x|}{dx} = \text{sgn}(x)$$

Thus,

$$\frac{dF}{dx} = \sum_{i=1}^N \text{sgn}(x_i)$$

We should notice that in derivative is 0 only if the number of positive elements is equal to the number of negative elements. Meanwhile, $x = \text{median}$ can make sure that the number of elements which are less than median and the number of elements which are greater than median is equal. Plus, if $x < \text{median}$ and then the derivative is negative; if $x > \text{median}$ and then the derivative is positive.

Thus, median is an optimal solution.

Proof 2. is as follows: Suppose the length is odd and $T \leq M$. We can conclude that:

$$x_1 \leq x_2 \leq \dots \leq x_s \leq \dots \leq T \leq \dots \leq x_{t-1} \leq x_t = M \leq x_{t+1} \leq \dots \leq x_N \quad (t = \frac{n-1}{2})$$

$$\begin{aligned} F(T) &= \sum_{i=1}^N (x_i - T) \\ &= \sum_{i=1}^s (T - x_i) + \sum_{i=s+1}^N (x_i - T) \\ &= \left[\sum_{i=1}^{t-1} (T - x_i) - \sum_{i=s+1}^{t-1} (T - x_i) \right] + \left[\sum_{i=s+1}^{t-1} (x_i - T) + 0 + \sum_{i=t+1}^N (x_i - T) \right] \\ &= \left[\sum_{i=1}^{t-1} (T - M + M - x_i) - \sum_{i=s+1}^{t-1} (T - x_i) \right] + \left[\sum_{i=s+1}^{t-1} (x_i - T) + \sum_{i=t+1}^N (x_i - M + M - T) \right] \quad (1) \\ &= \sum_{i=1}^{t-1} (M - x_i) + (t-1)(T - M) + 2 \sum_{i=s+1}^{t-1} (x_i - T) + \sum_{i=t+1}^N (x_i - M) + (n-t)(M - T) \\ &= \sum_{i=1}^{t-1} (M - x_i) + \sum_{i=t+1}^N (x_i - M) + 2 \sum_{i=s+1}^t (x_i - T) + (n-2t+1)(M - T) \\ &= \sum_{i=1}^{t-1} (M - x_i) + \sum_{i=t+1}^N (x_i - M) + 2 \sum_{i=s+1}^t (x_i) - 2(t-s) * T \end{aligned}$$

Thus, if we want to minimize the $F(T)$, we just need to maximize T , which means when $T = M$ we can get the minimum of $F(T)$. It is similar when $T \geq M$ and we can insert a certain number between the middle two numbers to make the array odd.

□

2. Given a string that consists of only uppercase English letters, you can replace any letter in the string with another letter at most k times. Find the length of a longest substring containing all repeating letters you can get after performing the above operations.

Note: Both the string's length and k will not exceed 104.

Example:

Input:

$s = \text{"AABABBA"}, k = 1$

Output:

4

Explanation:

Replace the one 'A' in the middle with 'B' and form "AABBBBA". The substring "BBBB" has the longest repeating letters, which is 4.

Input:

string s;

int k;

Output:

return the length of the longest substring.

3. You are given an array x of n positive numbers. You start at point $(0,0)$ and moves $x[0]$ metres to the north, then $x[1]$ metres to the west, $x[2]$ metres to the south, $x[3]$ metres to the east and so on. In other words, after each move your direction changes counter-clockwise.

Write a one-pass algorithm with $O(1)$ extra space to determine, if your path crosses itself, or not.

Example 1:

Given $x = [2, 1, 1, 2]$

Return true (self crossing)

Example 2:

Given $x = [1, 2, 3, 4]$

Return false (not self crossing)

Example 3:

Given $x = [1, 1, 1, 1]$

Return true (self crossing)

Input:

int $x[]$: the input array.

int N : length of x .

Output:

return true or false.
